

Advanced Machine Learning

Course plan:

1. Machine Learning fundamentals
2. Classification problem revisited: decision trees
3. Neural network architectures (part one: deep NN & CNN)
4. Basics of signal and image processing
5. Application of NN for image processing: (classification, segmentation, frameworks)
6. Neural network architectures (part two, advanced ideas: RNNs, attention, autoencoders, GANs)
7. DETR, weakly supervised learning, graph NN

machine learning fundamentals

What is machine learning?

Family of computer methods that improve automatically through experience

- without being *explicitly* programmed to

What kind of problems we would like (to be able) to solve?

- the early days of AI: problems that are intellectually difficult for humans but straightforward for computers
- nowadays, the *true* challenge to AI are tasks easy for people to perform but **hard to be described formally**
 - like recognizing spoken words or faces on images

The machine learning (ML) solution to these problems:

- allow computers to learn from experience and understand the world in terms of a hierarchy of concepts
this approach avoids the need for human to specify all the knowledge that the computer needs.

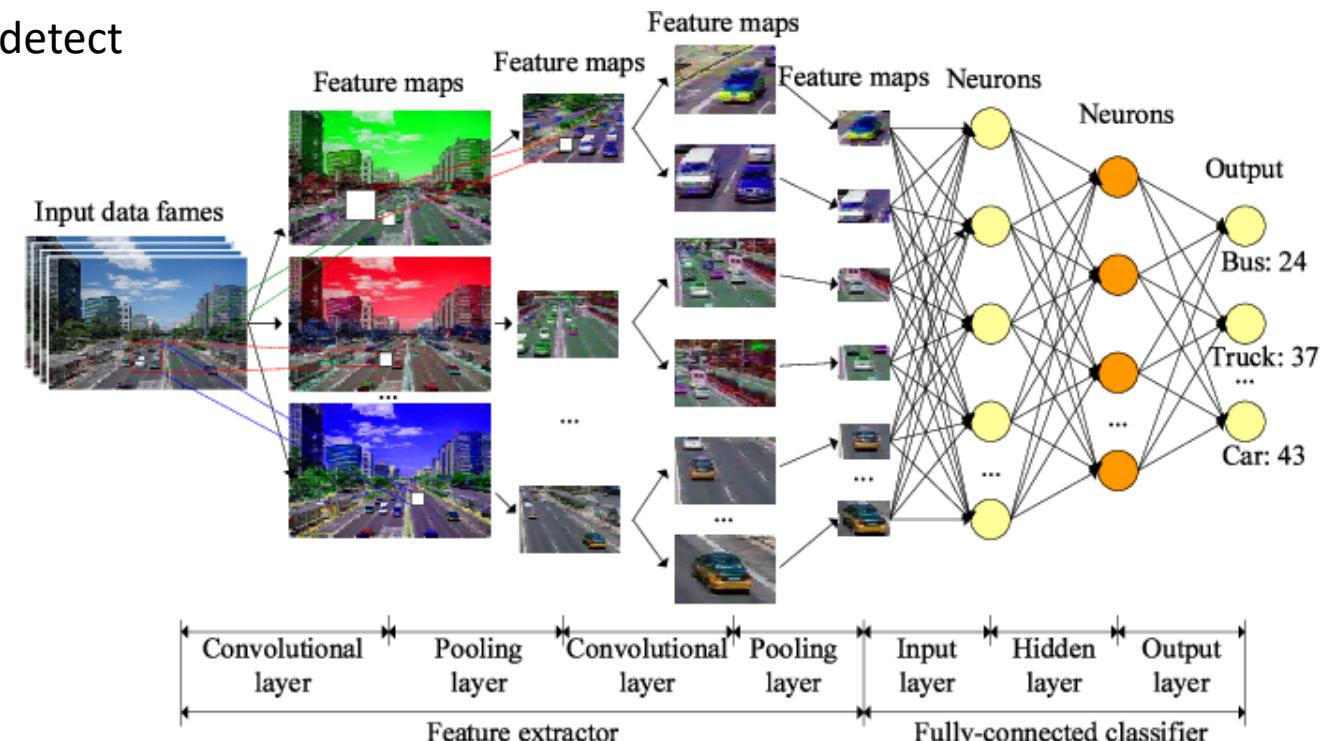

The hierarchy of concepts enables the computer to learn complicated concepts by building them out of simpler ones

- representations of data with multiple (**deep**) levels or *layers* of abstraction

What is machine learning?

If we draw a graph showing how these concepts are built on top of each other, the graph is *deep*, with many layers. For this reason, we call this approach to AI **deep learning**

Here each layer is automatically trained to learn and detect different features on the input image

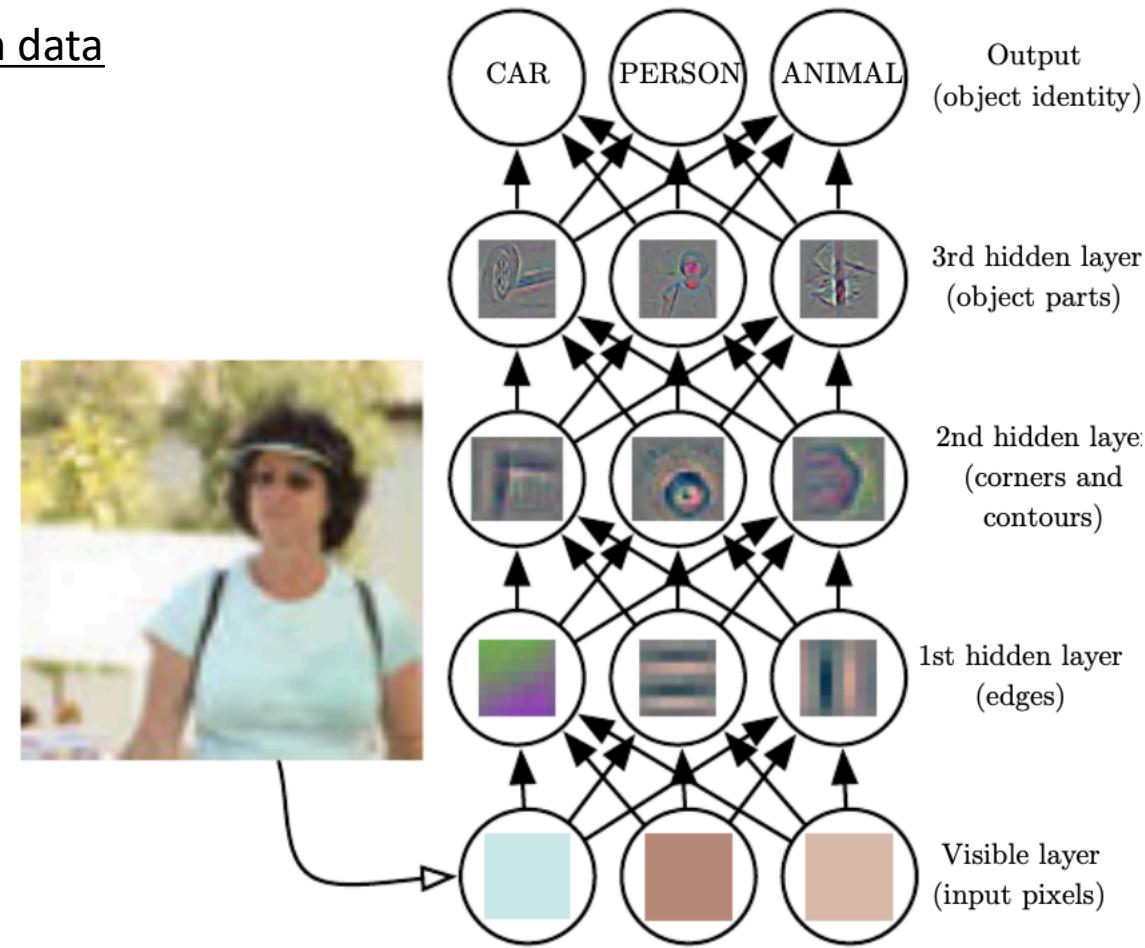

What is machine learning?

How to efficiently solve these problems – automatically learn from data

A machine learning algorithm is an algorithm that is able to efficiently learn from data

To sum up:

- deep learning solves problems by introducing representations that are expressed in terms of other, simpler representations
- deep learning enables the computer to automatically learn complex concepts out of simpler ones

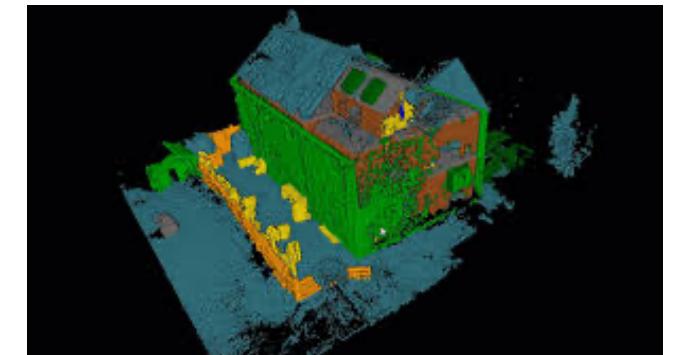

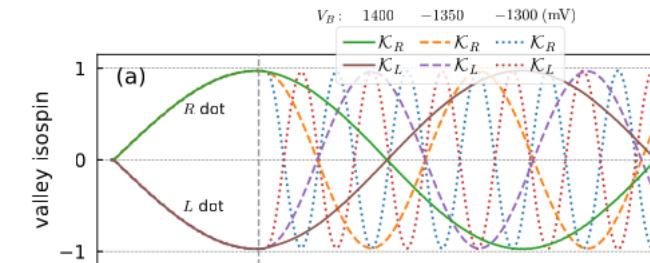

What is machine learning?

Typical ML tasks:

- classification $f : \mathbb{R}^n \rightarrow \{1, \dots, k\}$.
- regression $f : \mathbb{R}^n \rightarrow \mathbb{R}$
- transcription (OCR/ASR), translation
 - extract word and whole sentences from written or spoken data
- anomaly detection
 - detect events or objects that are unusual in a given context
- synthesis and sampling
 - generate new examples that are similar to those in the training data
- denoising
 - predict clean sample x from the corrupted one \tilde{x}

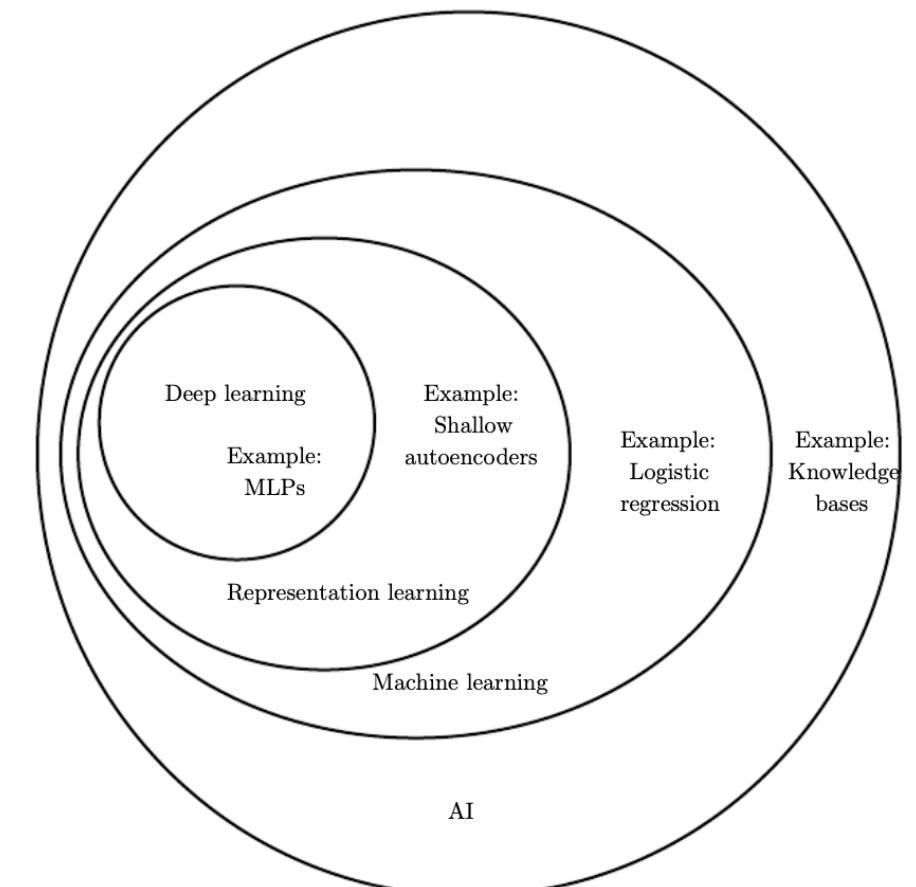

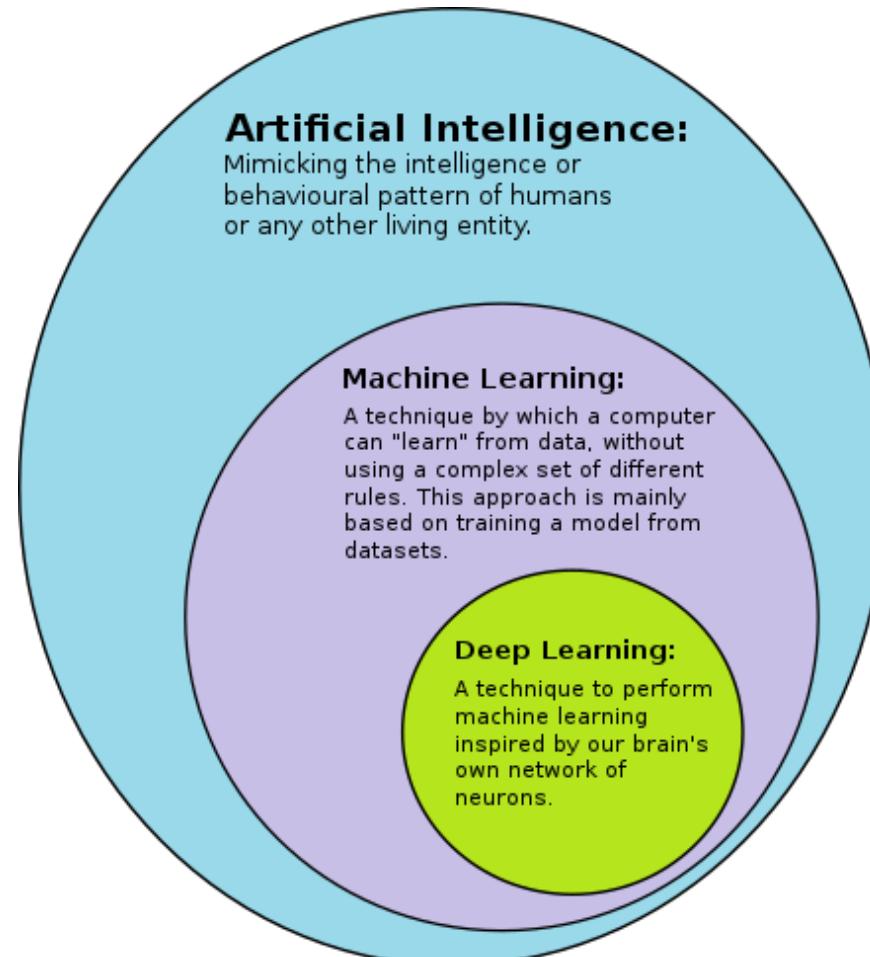

Example data dimensionality:

- 1d signal
- 2d image
- 3d point cloud

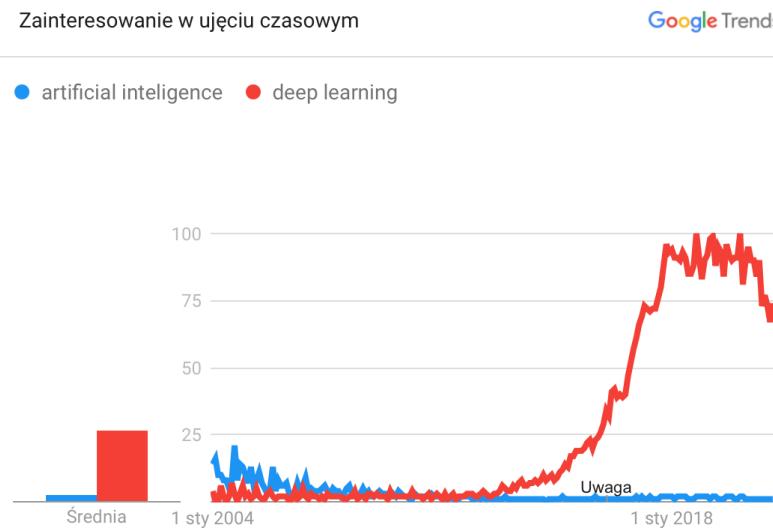

What is machine learning?

To summarize AI technologies

Why deep learning became so popular?

Why deep learning became a crucial technology in last few years?

- Increasing dataset sizes
- a dumb algorithm with lots of data beats a clever algorithm with a modest amount of data
- is connected with increasing size of models

MNIST Dataset

ImageNet Dataset

Russakovsky, O., Deng, J., Su, H., Krause, J., Satheesh, S., Ma, S., ... & Fei-Fei, L. (2015). *Imagenet large scale visual recognition challenge*. arXiv preprint arXiv:1409.0575. [\[web\]](#)

3

image-net.org: 14 M images, 1000 categories

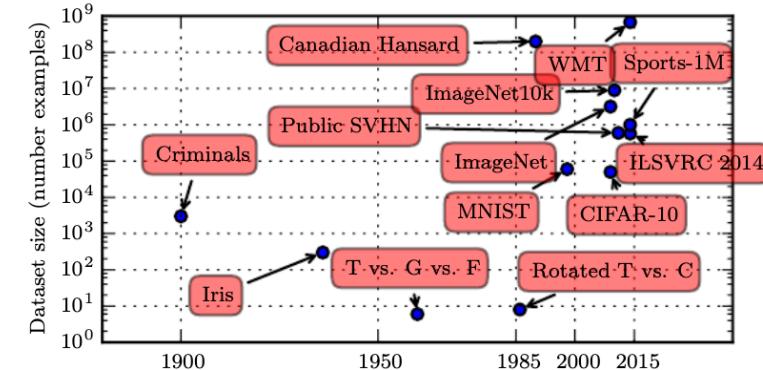

Figure 1.8: Increasing dataset size over time. In the early 1900s, statisticians studied datasets using hundreds or thousands of manually compiled measurements (Garson, 1900;

<https://www.deeplearningbook.org/contents/intro.html>

- 60,000 examples, 10 classes
- features: 28x28x1
- <http://yann.lecun.com/exdb/mnist/>

What is COCO?

COCO is a large-scale object detection, segmentation, and captioning dataset. COCO has several features:

- ✓ Object segmentation
- ✓ Recognition in context
- ✓ Superpixel stuff segmentation
- ✓ 330K images (>200K labeled)
- ✓ 1.5 million object instances
- ✓ 80 object categories
- ✓ 91 stuff categories
- ✓ 5 captions per image
- ✓ 250,000 people with keypoints

Why deep learning became so popular?

Deep learning models size vs human brain

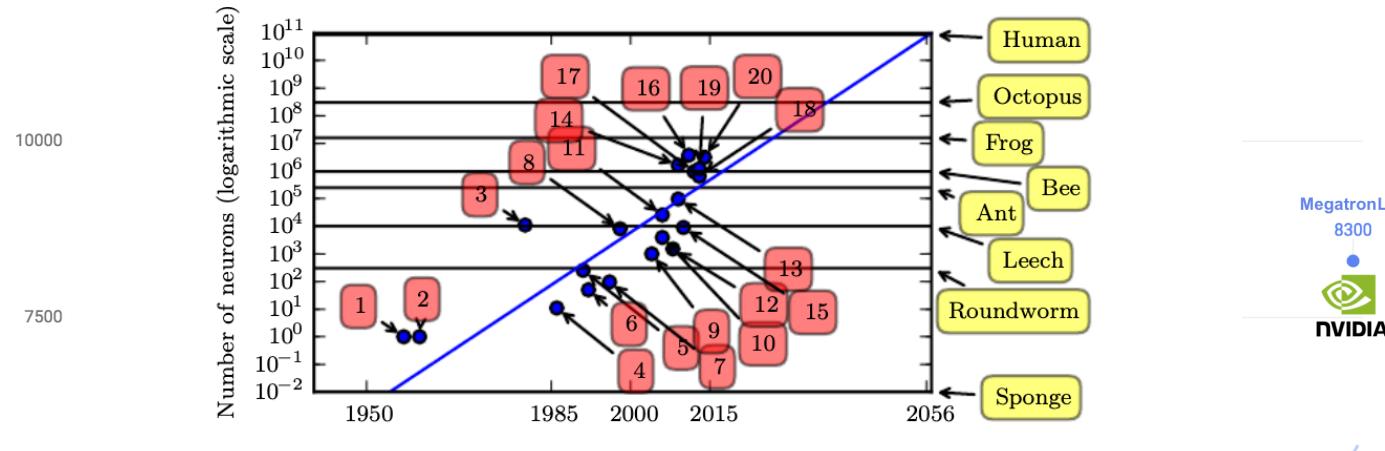

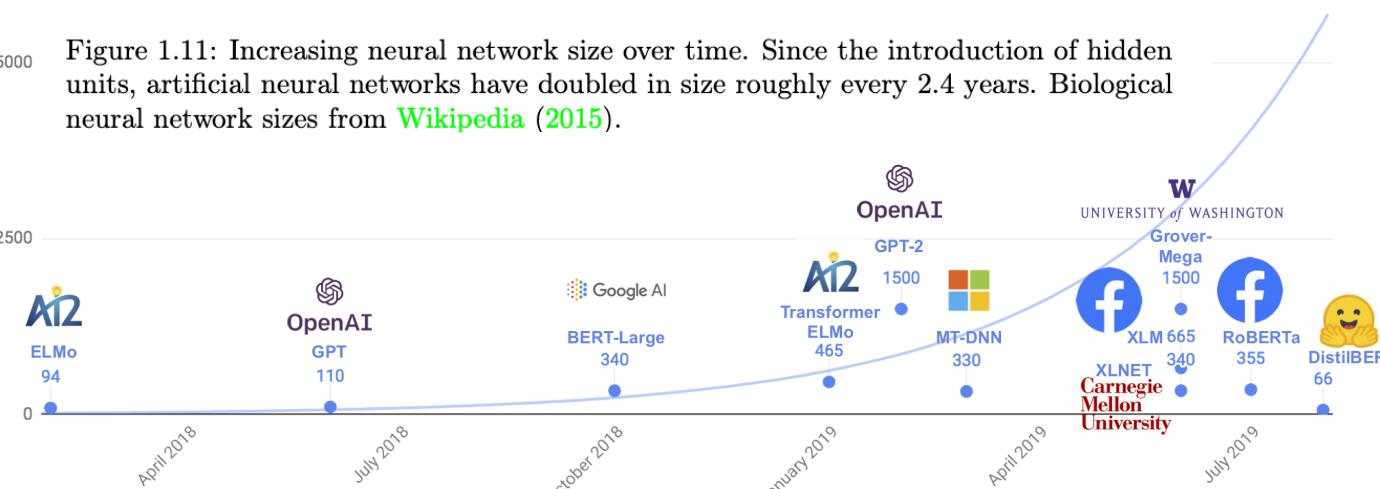

Figure 1.11: Increasing neural network size over time. Since the introduction of hidden units, artificial neural networks have doubled in size roughly every 2.4 years. Biological neural network sizes from [Wikipedia \(2015\)](#).

<https://www.deeplearningbook.org/contents/intro.html>
<https://medium.com/huggingface/distilbert-8cf3380435b5>

artificial neural network vs (human) brain - differences:

- number of connections: human brain has 10^5 times more connections in total
- topology: connections are randomly distributed, artificial networks have layered feedforward structure
- human brain is much faster in generating outputs
- brain structure is much more stable and resilient to errors (artificial networks are susceptible to attacks)
- brains are being in training mode continuously

ABSTRACT

In deep learning, models typically reuse the same parameters for all inputs. Mixture of Experts (MoE) models defy this and instead select *different* parameters for each incoming example. The result is a sparsely-activated model – with an outrageous number of parameters – but a constant computational cost. However, despite several notable successes of MoE, widespread adoption has been hindered by complexity, communication costs, and training instability. We address these with the Switch Transformer. We simplify the MoE routing algorithm and design intuitive improved models with reduced communication and computational costs. Our proposed training techniques mitigate the instabilities, and we show large sparse models may be trained, for the first time, with lower precision (bfloat16) formats. We design models based off T5-Base and T5-Large (Raffel et al., 2019) to obtain up to 7x increases in pre-training speed with the same computational resources. These improvements extend into multilingual settings where we measure gains over the mT5-Base version across all 101 languages. Finally, we advance the current scale of language models by pre-training up to trillion parameter models on the “Colossal Clean Crawled Corpus”, and achieve a 4x speedup over the T5-XXL model.¹

Machine learning approaches

Supervised learning:

- data is organized in pairs (input, expected output)
- problems: classification, regression
- SVM, decision trees, neural networks
- gaussian discriminant analysis, naive Bayes

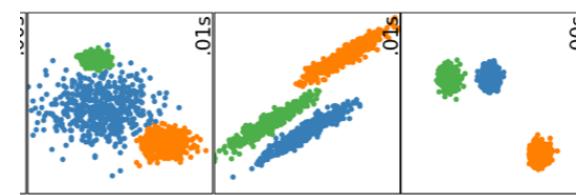

Training set: $\mathcal{D} = \{\langle \mathbf{x}^{[i]}, y^{[i]} \rangle, i = 1, \dots, n\}$,
"training examples"
Unknown function: $f(\mathbf{x}) = y$
Hypothesis: $h(\mathbf{x}) = \hat{y}$ ← sometimes
Classification Regression
 $h : \mathbb{R}^m \rightarrow \mathcal{Y}, \quad \mathcal{Y} = \{1, \dots, k\}$ $h : \mathbb{R}^m \rightarrow \mathbb{R}$

www.researchgate.net/project/software-defined-network-3

Unsupervised learning:

- in opposite to supervised learning, data is not labeled
- problems: clustering, dimensionality reduction
- PCA, LDA, k-means clustering

<https://scikit-learn.org>

Reinforcement learning

Example: Supervised vs Unsupervised

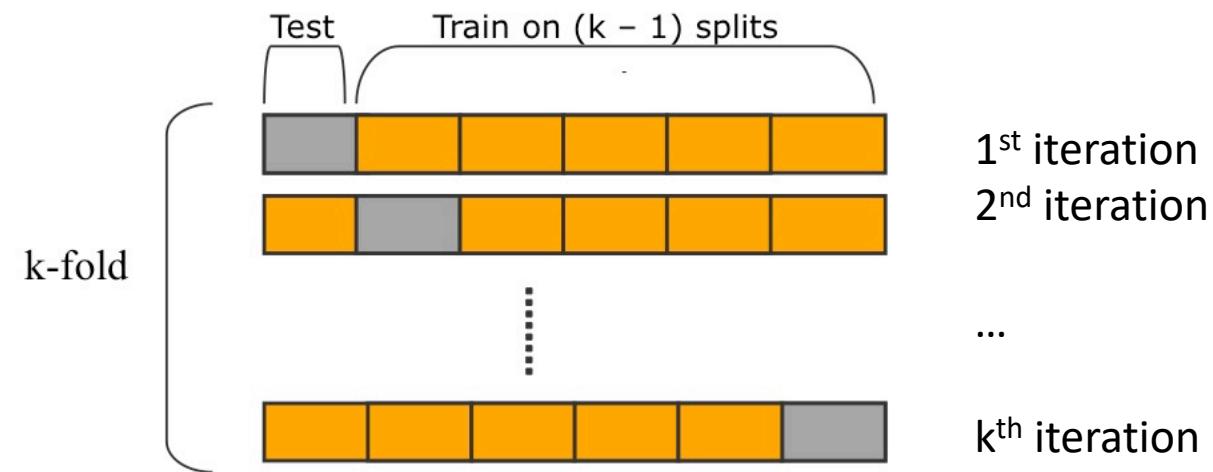

- Having N photos of different animals
- Supervised task (requires labeled data)
 - Train an algorithm to recognise given species on a photo.
Output: There is X on a photo.
 - Unsupervised task
 - Train an algorithm to group animals with similar features.
Output: No idea what it is, but it looks similar to these animals.

Learning scheme

How to perform learning and evaluate model performance

- divide dataset into **train** an **test** subsets
 - test should be evaluated on data *unseen* during training
- *k*-fold cross-validation

<https://aszokalski.github.io/AI/Cross-Validation.html>

- in practice, while testing big models,
we limit ourselves to only one *k*-fold iteration

Bias-variance tradeoff

The ability to perform well on previously unobserved inputs is called **generalization**:

- during learning we optimize model to have lowest **training error**,
- we want the generalization error, also called the **test error** to be low as well.

Training and testing error correspond to the two central challenges in machine learning: (model) **underfitting** and **overfitting**.

strongly recommended paper: <https://homes.cs.washington.edu/~pedrod/papers/cacm12.pdf>

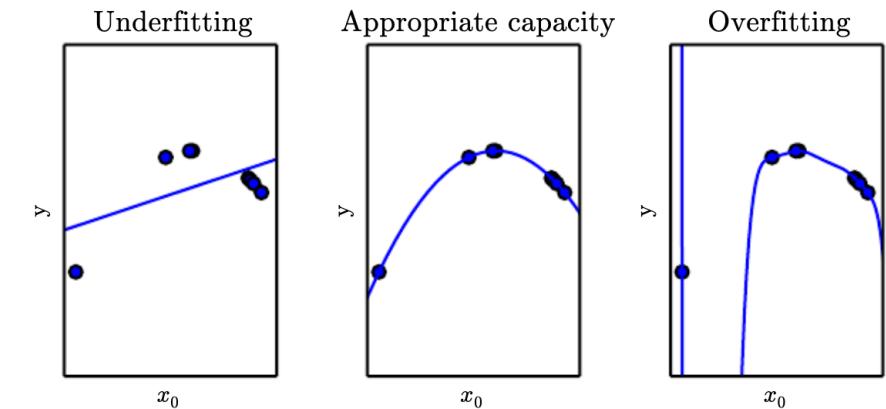

Bias-variance tradeoff

Underfitting: model is not able to obtain a sufficiently low error on the training set

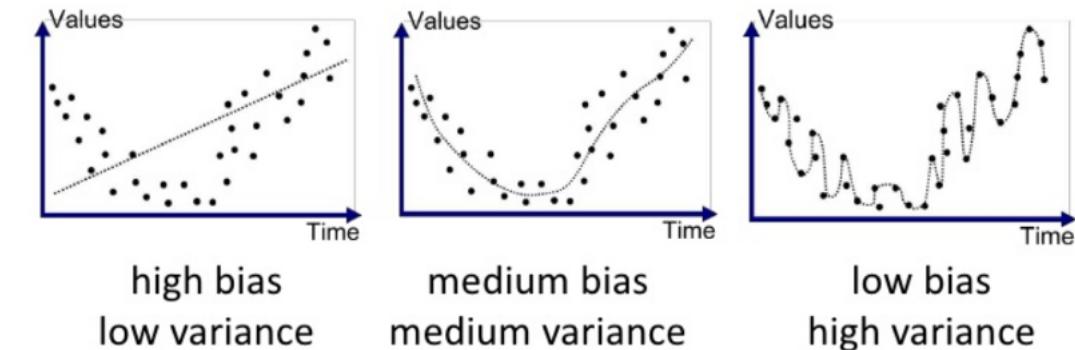

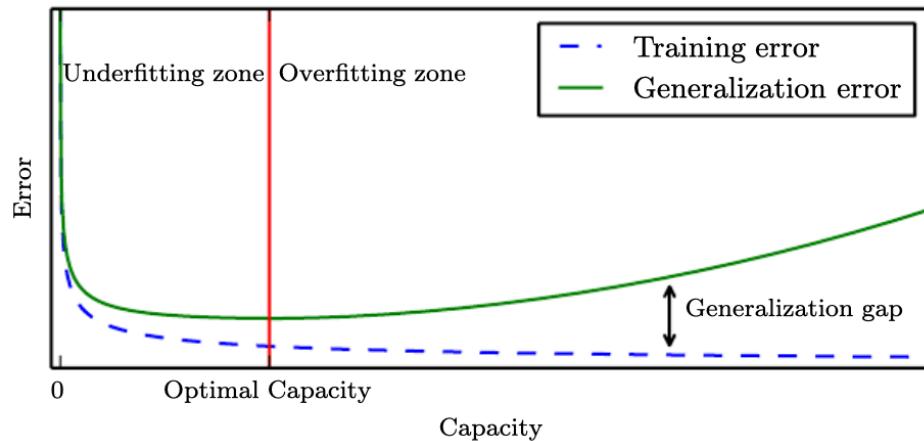

Overfitting occurs when the distance between the training and test error is too large

We can control whether a model is more likely to overfit or underfit by altering its **capacity**

Here capacity means degree of the fitted polynomial:

Bias-variance tradeoff

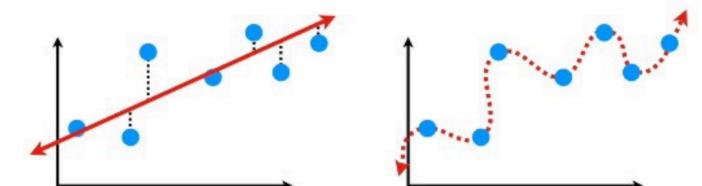

$$\text{MSE} = \mathbb{E}[(\hat{x}(t) - x(t))^2] = \text{Bias}(\hat{x}(t))^2 + \text{Var}(\hat{x}(t)),$$

with $\text{Bias}(\hat{x}(t)) = \mathbb{E}(\hat{x}(t)) - x(t)$

- High bias can cause an algorithm to miss the relevant relations in data (underfitting).
- High variance can cause an algorithm to model the random noise in the training data (overfitting).

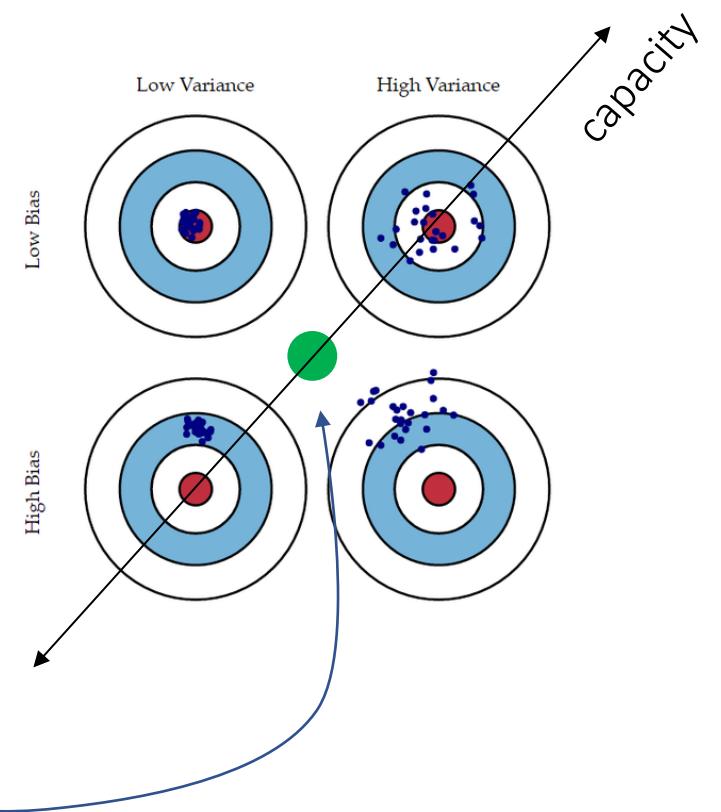

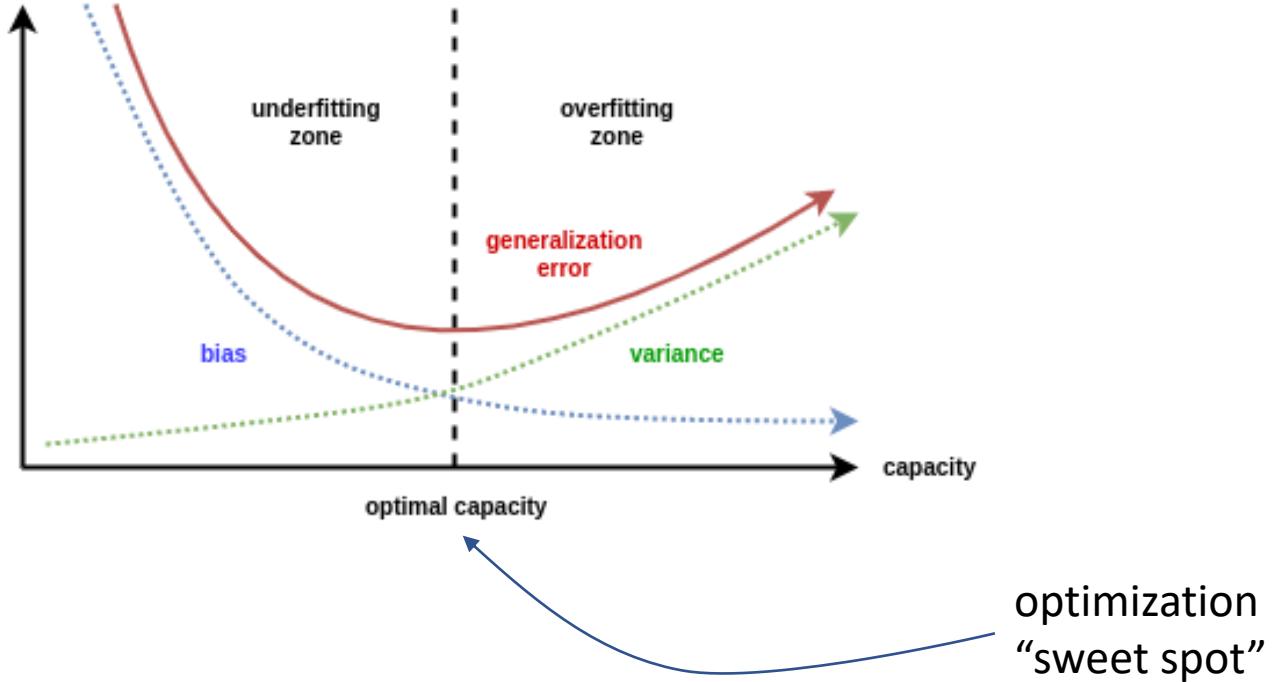

We can compare how well the **Straight Line** and the **Squiggly Line** fit the **training set** by calculating their sums of squares.

When the model tries to reduce bias it tends to overfit the data. Left fig have high bias & right fig have low bias.

Bias-variance tradeoff

To low bias will result in to high variance and vice versa

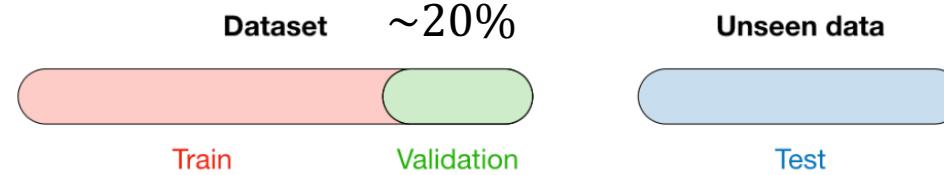

Avoiding overfitting: validation set

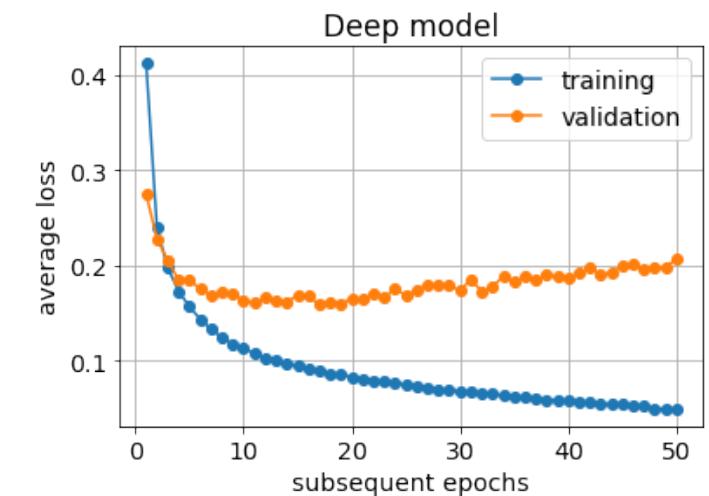

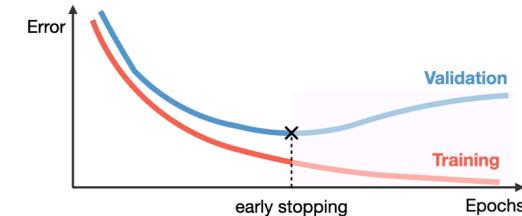

How to avoid overfitting

- The model should chosen/tuned (*hyperparameters*) to be as simple as possible but not simpler (Occam's razor), i.e. with appropriate capacity.

We need another subset (**validation** set) to estimate the generalization error during training, allowing for the model hyperparameters to be updated accordingly.

□ **Early stopping** — This regularization technique stops the training process as soon as the validation loss reaches a plateau or starts to increase.

training stopping moment is one of the hyperparameters to be tuned

Avoiding overfitting

How to avoid overfitting

- Do not train too long!
- Regularization: adding weight to loss function to prefer one type of solutions over other (e.g. with lower polynomial degree)
- Augmentation
- Increase dataset size (but new data should be coherent)
...a dumb algorithm with lots of data beats a clever algorithm with a modest amount of data...

| | Underfitting | Just right | Overfitting |
|-----------------------------|--|---|---|
| Symptoms | <ul style="list-style-type: none">• High training error• Training error close to test error• High bias | <ul style="list-style-type: none">• Training error slightly lower than test error | <ul style="list-style-type: none">• Very low training error• Training error much lower than test error• High variance |

| Possible remedies | <ul style="list-style-type: none">• Complexify model• Add more features• Train longer | | <ul style="list-style-type: none">• Perform regularization• Get more data |

No free lunch theorem

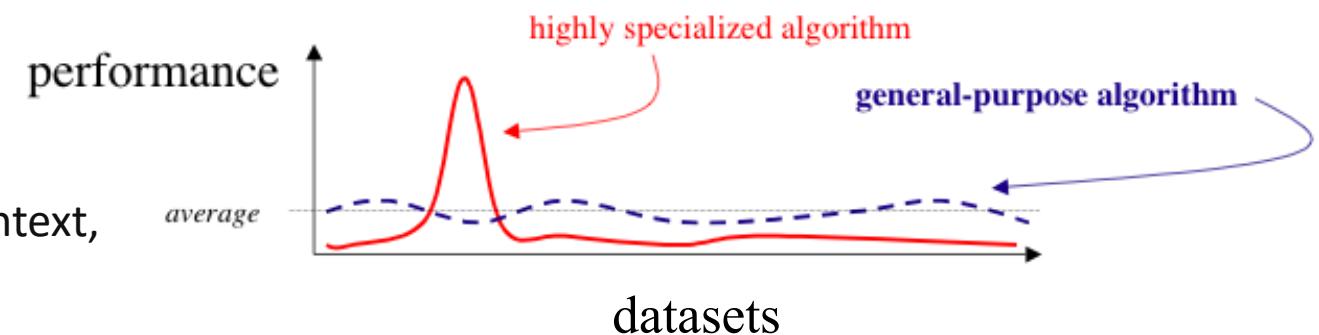

Suppose that we have all possible domains (datasets) for a given problem (e.g. image classification) and need to compare two methods A and B:

No free lunch theorem states that:

- mean performance for algorithms A and B averaged over the all possible datasets is the same,
- this holds true even when one of the algorithms is just random guessing.

There is no such thing as a single, universally-best machine learning algorithm, and there are no *a priori* reasons to favor one algorithm over all others.

- we can't get good machine learning for *free*.
- we must use knowledge about our data and the context, to select an appropriate machine learning model.

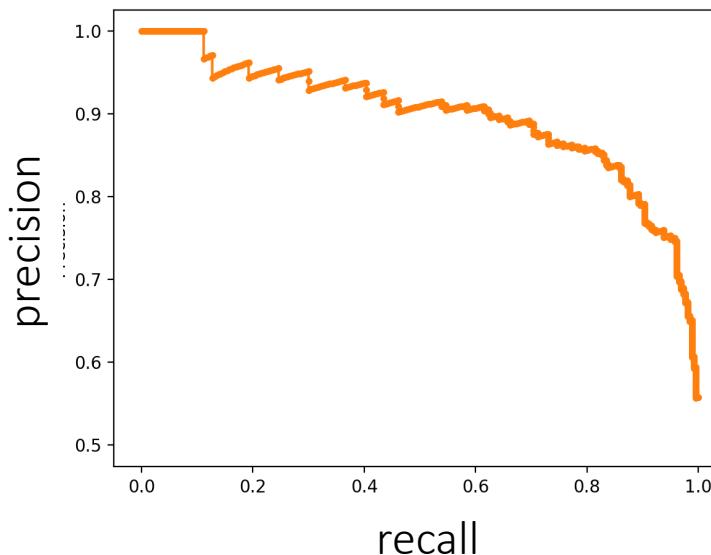

Precision-recall tradeoff

classification and detection metrics:

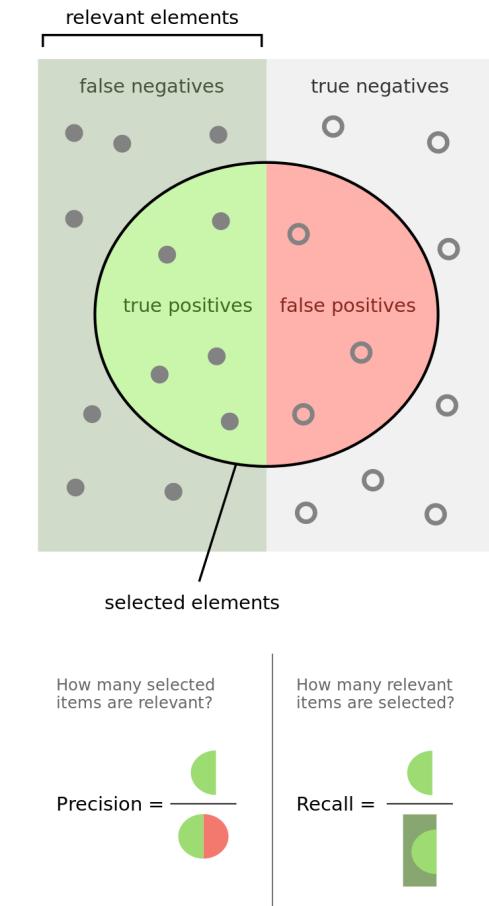

- information stored in *confusion matrix* are used to calculate:
 - accuracy,
 - precision, recall,
 - F1 score

precision-recall tradeoff:

- if you increase precision (by model tuning), it will reduce recall, and vice versa.

| | | Predicted class | |
|--------------|---|---------------------------------------|--|
| | | + | - |
| Actual class | + | TP True Positives | FN False Negatives Type II error |
| | - | FP False Positives Type I error | TN True Negatives |

| Metric | Formula | Interpretation |
|-----------------------|-------------------------------------|---|
| Accuracy | $\frac{TP + TN}{TP + TN + FP + FN}$ | Overall performance of model |
| Precision | $\frac{TP}{TP + FP}$ | How accurate the positive predictions are |
| Recall Sensitivity | $\frac{TP}{TP + FN}$ | Coverage of actual positive sample |
| Specificity | $\frac{TN}{TN + FP}$ | Coverage of actual negative sample |
| F1 score | $\frac{2TP}{2TP + FP + FN}$ | Hybrid metric useful for unbalanced classes |

ML applications

ML applications

- Image recognition
 - Google Maps - finding licence plates and faces; extracting street names and building numbers
 - Facebook - recognising similar faces
- Speech recognition
 - Microsoft - Cortana
 - Apple - Siri
- Natural Language Processing
 - Google Translate - machine translation
 - Next Game of Thrones Book - language modeling
- Misc
 - PayPal - fraud alert
 - Netflix, Amazon - recommendation system

ML applications: deep fake

Deep ML: potential dangers

Deep fake wars:
Facebook is actively seeking for
(ML) tools to detect/eliminate
deep fake information

ML frameworks

ML solution are nowadays extremely easy to implement

- we are able to build quite a complex deep neural network model in a 5 minutes
(of course learning itself can take 5 days ;-)

Main tools for this course
